ABSTRACT

Pyrolysis of palm kernel shell in a fixed-bed reactor was studied in this paper. The objectives were to investigate the effect of pyrolysis temperature and particle size on the products yield and to characterize the bio-oil product. In order to get the optimum pyrolysis parameters on bio-oil yield, temperatures of 350, 400, 450, 500 and 550 °C and particle sizes of 212–300 µm, 300–600 µm, 600µm–1.18 mm and 1.18–2.36 mm under a heating rate of 50 °C min⁻¹ were investigated. The maximum bio-oil yield was 38.40% at 450 °C with a heating rate of 50 °C min⁻¹ and a nitrogen sweep gas flow rate of 50 ml min⁻¹. The bio-oil products were analysed by Fourier transform infra-red spectroscopy (FTIR) and gas chromatography–mass spectroscopy (GCMS). The FTIR analysis showed that the bio-oil was dominated by oxygenated species. The phenol, phenol, 2-methoxy- and furfural that were identified by GCMS analysis are highly suitable for extraction from the bio-oil as value-added chemicals. The highly oxygenated oils need to be upgraded in order to be used in other applications such as transportation fuels.

Keywords: Biomass; renewable energy; pyrolysis; palm kernel shell; bio-oil; char.

INTRODUCTION

Renewable energy can be considered as an alternative to conventional energy sources [1, 2]. It is capable of assuring secure and sustainable development while energy consumption is increasing and fossil fuels are limited, with a growing population and economic developments [3-6]. Currently, biomass is highlighted as a promising renewable energy source due to environmental problems caused by the combustion of fossil fuels and the shortage of fossil fuels expected in the future. Fast pyrolysis has potential prospects for the thermo-chemical conversion of lignocellulosic biomass into liquid fuels because of its higher yield and quality of liquid oil compared to other techniques [7]. Pyrolysis is the thermal conversion of organics in the absence of oxygen. In this biomass, pyrolysis commonly refers to lower temperatures in a 300 °C– 800 °C thermal process producing liquids (bio-oil), solid (char) and gases. Pyrolysis is one of the most recent renewable energy processes and promises high yields of liquid (75%) with a minimum of gas and bio-char under a controlled environment [8-11]. However, among the thermochemical conversion methods, pyrolysis is the most suitable method to produce bio-oil as the main product, compared to gasification and combustion. In the pyrolysis process, when the components are quickly quenched, the volatile components condense to bio-oil. The bio-oil can be substituted for fuel oil in many static

applications including boilers, combustion engines and turbines for the generation of electricity, or can be subjected to further treatment and processes to produce secondary products such as higher value and quality fuel or chemical products [12]. Biomass utilization gives the possibility of generating value-added products such as chemicals or activated carbons, which means an attractive economic and technological solution [13-16]. The major contributor of biomass in Malaysia that has the potential to generate energy is the palm oil industry, where most of the wastes are empty fruit bunches (EFB), mesocarp fibre, palm kernel shells (PKS), and palm kernel cake (residue). Among the palm oil wastes, PKS has a great potential as a source of biomass to develop renewable energy sources. Since the PKS produced from palm oil mills is abundant, cheap and does not require significant effort to collect, it is currently used as a low energy efficiency fuel for boilers [17]. Meanwhile, converting palm kernel shell to bio-oil under a thermal process provides a greater benefit to use as biomass energy to replace fossil fuels, and it minimizes the disposal problems associated with the generation of agricultural by-products. In this study, the pyrolysis of palm kernel shell was conducted in a fixed-bed reactor. The effects of the pyrolysis parameters on the product yield were investigated and bio-oil product characterization was explored.

MATERIAL AND METHOD

Material

The biomass used for the pyrolysis process was palm kernel shell (PKS). The PKS was collected from Malpom Industries Sdn Bhd, Jalan Bukit Changkat, Nibong Tebal, Pulau Pinang. PKS is the shell material left after the nut has been removed after crushing in the palm oil mill. It is dried in the oven at a temperature of 105 °C for 2 hours to remove the moisture content. By using a crusher, the palm kernel shells are reduced to a small size. The palm kernel shells are sieved using a sieve shaker to separate the particle sizes needed. The palm kernel shell collected had particle sizes of 212–300 µm, 300–600 µm, 600µm–1.18 mm and 1.18–2.36 mm in diameter. The proximate analysis and ultimate analysis are shown in Table 1.

Table 1. Proximate and ultimate analysis of palm kernel shell.

Proximate analysis	Value (wt%)	Ultimate analysis	Value (wt%)
Moisture content	6.33	Carbon	44.29
Volatile matter	62.82	Hydrogen	9.01
Fixed carbon	19.10	Nitrogen	2.37
Ash	11.75	Sulphur	1.20
		Oxygen ^a	43.13

^aBy difference

Pyrolysis Process

A fixed bed reactor, R-301 Series Catastest Reactor System, was used for the biomass pyrolysis experiments. The reactor tube was filled with 5 ± 0.5 g palm kernel shell with 212–300 µm, 300–600 µm, 600 µm–1.18 mm and 1.18–2.36 mm particle sizes. A heating rate of 50 °C/min and a constant flow rate of N₂ at 50ml/min were used in the pyrolysis experiment in order to achieve an inert atmosphere during pyrolysis. The

pyrolysis yield results from the various parameters of the pyrolysis process were investigated by identifying the effects of temperature (350 °C, 400 °C, 450 °C, 500 °C and 550 °C) and the palm kernel shell particle size (212–300 µm, 300–600 µm, 600µm–1.18 mm and 1.18–2.36 mm). The char and bio-oil products were weighed to calculate the percentage of the yield. The gas produced was calculated by differences. The bio-oil was analysed using Fourier transform-infrared (FT-IR/FT-NIR Spectrometer Spectrum 400, Perkin Elmer) and gas chromatography mass spectroscopy (GC/MS-GP 2010 Series, Shidmadzu).

RESULTS AND DISCUSSION

Effect of Temperature and Particle Size on Pyrolysis Product

Figure 1 shows the effect of temperature on the product yields for temperatures of 350, 400, 450, 500 and 550 °C with 600µm–1.18m palm kernel shell particle sizes and a heating rate of 50 °C/min. The optimum temperature was 450 °C, producing the maximum bio-oil yield of 38.40%. The result shows that as the temperature begins to increase from 350 to 450 °C, the bio-oil yield increases to the maximum from 28.90 wt% to 38.40 wt%. Then, from 450 °C to 500 °C, the bio-oil yield dropped sharply by about 10.56 wt%, from 39.40 wt% to 27.84 wt%. The yield remained stable until the final pyrolysis temperature, 550 °C. The bio-oil product decreased at pyrolysis temperatures of 450 to 550 °C due to the decrease of the organic and specific products and secondary cracking of volatiles at temperatures above 500 °C [18]. Above this temperature, the bio-oil yield decreased with the conjunction of releasing more gas products due to secondary cracking [19]. It was concluded that the optimum temperature for bio-oil production was 450 °C in the present experimental conditions.

Figure 1. Effect of pyrolysis temperature on product yield.

Figure 2 shows that the maximum bio-oil yield of 38.40% was obtained with particle sizes of 600 µm–1.18 mm. The smallest particle size of 212–300 µm produced the lowest bio-oil yield of 12.53%, with a char yield of 29.06% and gas yield of 58.41%. Besides that, the largest particle size of 1.18–2.36 mm produced a bio-oil yield of 30.49%, which was 7.81% less than the highest bio-oil yield produced. This was due to the fact that the smaller size particles were either overheated or blown too quickly from the reactor before pyrolysis took place, so producing less bio-oil. On the other hand, the larger particle sizes were not heated up sufficiently rapidly, causing

incomplete pyrolysis and so producing less bio-oil [20]. Another study by Phan et al. [21] on rice straw showed that the oil yield decreased from 52.76% to 48.52% as the particle size increased from the range 500 μm –1.00 mm to the range 1.00–2.00 mm. This is because, when the biomass particle size increases, the distance from the biomass particle's surface to its centre increases, which delays the heat transfer rate from the hot material to cold biomass. Therefore, the bio-oil yield decreases [22].

Figure 2. Effect of particle size on product yield.

Bio-oil Characterization

The Fourier transform infra-red spectroscopy (FT-IR) analysis was conducted on bio-oil obtained from the optimum pyrolysis parameter. The O-H stretching vibrations between 3200 and 3600 cm^{-1} indicate the presence of phenol and alcohols. The C-H stretching vibrations between 2800 and 3000 cm^{-1} and C-H deformation vibrations between 1350 and 1465 cm^{-1} indicate the presence of alkanes. The C=O stretching vibrations between 1640 cm^{-1} and 1780 cm^{-1} represent the presence of ketones, aldehydes, carboxylic acids and their derivatives. The absorbance peaks between 1580 cm^{-1} and 1680 cm^{-1} represent C=C stretching vibrations indicative of alkenes and aromatics. Absorptions possibly due to C-O vibrations from carbonyl components (i.e., alcohols, esters, carboxylic acids or ether) occur between 950 cm^{-1} and 1300 cm^{-1} of the bio-oil. Absorbance peaks between 650 and 900 cm^{-1} indicate the possible presence of single, polycyclic and substituted aromatic groups [23]. Table 2 shows the FTIR analysis of the bio-oil.

Gas chromatography-mass spectroscopy (GCMS) analysis as shown in Table 3 was carried out on the optimum parameter of bio-oil yield. The highest values of the peak areas of possible compounds were phenol, phenol, 2-methoxy- and furfural, with 39.52%, 7.27% and 5.20% respectively. The concentrations of phenol and its derivative were very high, indicating the suitability of the oil to be considered for value-added chemicals. In addition, it is possible to deoxygenate the bio-oil to obtain higher-grade fuel [24].

Table 2. FTIR functional group compositions of biomass bio-oil.

Frequency range (cm ⁻¹)	Group	Class of compound
3200 - 3600	O—H stretching	Polymeric O—H, water impurities
3000 - 2800	C—H stretching	Alkanes
1780 - 1640	C=O stretching	Ketones, aldehydes, carboxylic acids
1680 - 1580	C=C stretching	Alkenes
1550 - 1490	—NO ₂ stretching	Nitrogenous compounds
1465 - 1350	C—H stretching	Alkanes
950 - 1300	C—O stretching	Primary, secondary and tertiary alcohol,
	O—H stretching	Phenol, esters, ethers
900 - 650		Aromatic compounds

Table 3. Identification and peak areas of chemical compounds in biomass pyrolysis oil.

Chemical compounds	Peak area (%)	Chemical compounds	Peak area (%)
1-Hydroxy-2-butanone	1.94	1,2-benzonediol	4.97
Acetic acid, methyl ester	4.76	2-methoxy-5-methylphenol	1.72
Propylone oxide	1.49	1-hexadecanone, 1-cyclopentyl-	1.52
Furfural	5.20	1,2-benzebediol,3-methoxy-	3.20
2-propanone, 1-(acetyloxy)	2.26	1,2-benzenediol,3-methyl-	1.31
2(5H)-furanone	1.95	3-nitropropanoic acid	1.72
1-piperidinepropanonitrile	1.72	Phenol,2,6-dimethoxy-	6.76
Phenol	39.52	1,2,3-trimethoxybenzene	1.71
1,2-cyclopentanedione,3-methyl-	1.98	Benzoic acid, 4-hydroxy-	4.22
Phenol, 2-methoxy-	7.27	.beta-D-glucofuranone,1,6-anhydro-	4.78

CONCLUSIONS

The palm kernel shell was pyrolyzed in a R-301 Catalyst Reactor System to obtain the pyrolysis products, which were bio-oil, char and gas. The maximum yield of bio-oil was 38.4 wt% achieved at a pyrolysis temperature of 450 °C, heating rate of 50 °C/min and particle size of 600 µm–1.18 mm. The results showed that the bio-oil was highly oxygenated, containing a high fraction of phenol-based compound. FT-IR analysis showed that the liquid was highly dominated by oxygenated species. Obviously, the highly oxygenated oil needs to be upgraded in order to raise the heating values before it can be used as industrial fuel. Phenol, phenol, 2-methoxy- and furfural were identified by GC-MS analysis and these are very suitable for extraction from the bio-oil for value-added chemicals.
